June 2024

The views expressed herein are those of the authors and not necessarily those of the Federal Reserve Banks of New York or any other person affiliated with the Federal Reserve System.

# Motivation

- Countries around the world have suffered the highest inflation of the last four decades
  - Witnessing at the same time:
    - ▶ Collapse and rebound in domestic demand, GDP and international trade
    - ▶ Consumption substitution across sectors (goods for services and back)
    - ▶ Labor shortages (pandemic/lockdowns and recovery)
  - **Global supply chains played a critical role in amplifying shocks within and across borders**
- ⇒ Macro/central banks “woke up” to importance of supply shocks and production resilience
- ⇒ **Future risks:** geopolitical, climate change, fragmentation of production

# Importance of Country-Sector Dimension: Production and Trade Network (65 by 44)

# We quantify the well-known narrative

*“Many viewed the sudden upturn in inflation as mostly a function of pandemic-related shifts in the composition of demand, a disruption of supply chains, and a sharp decline in labor supply.*

*The resulting supply and demand imbalances led to large increases in the prices of a range of items, especially goods ... But in the fourth quarter of 2021, the data clearly changed ... with only gradual progress in restoring global supply chains, and relatively few workers rejoining the labor force ... A new shock arrived in February 2022, when Russia invaded Ukraine, resulting in a sharp increase in energy and other commodity prices ... it was clear that bringing down inflation would depend both on the unwinding of the pandemic-related demand and supply distortions and on our tightening of monetary policy, which would slow the growth of aggregate demand, allowing supply time to catch up.”*

*Remarks from Jay Powell, 24th Jacques Polak Annual Research Conference, IMF, 2023.*

**Develop a new global network model to quantify price effects of demand-supply imbalances**

**⇒ open economy channels are important—transmission of cost-push and demand shocks**

# We quantify the well-known narrative

*"Many viewed the sudden upturn in inflation as mostly a function of pandemic-related shifts in the composition of demand, a disruption of supply chains, and a sharp decline in labor supply.*

*The resulting supply and demand imbalances led to large increases in the prices of a range of items, especially goods ... But in the fourth quarter of 2021, the data clearly changed ... with only gradual progress in restoring global supply chains, and relatively few workers rejoining the labor force ... A new shock arrived in February 2022, when Russia invaded Ukraine, resulting in a sharp increase in energy and other commodity prices ... it was clear that bringing down inflation would depend both on the unwinding of the pandemic-related demand and supply distortions and on our tightening of monetary policy, which would slow the growth of aggregate demand, allowing supply time to catch up."*

## Develop a new global network model to quantify price effects of demand-supply imbalances

⇒ **open economy channels are important—transmission of cost-push and demand shocks**

- Once importance of supply side shocks are understood, inflation coming down quickly is basic economics
- But that happening without an increase in unemployment is not basic economics!
- Our paper can account for disinflation without a recession theoretically, while quantifying role of supply shocks (both supply chains and energy) and demand shocks on inflation

## Our paper

- Estimate a multi-country multi-sector New Keynesian model to quantify the drivers of the pandemic-era inflation: Today 4 by 44—United States, Euro Area, Russia, China+RoW
- A rich set of sectoral and aggregate shocks that transmit through the global trade and production network.
- Can match observed headline inflation rates and changes in sector-level prices, wages, and exchange rates. (**nothing targeted**)

# Our paper

- Estimate a multi-country multi-sector New Keynesian model to quantify the drivers of the pandemic-era inflation: Today 4 by 44—United States, Euro Area, Russia, China+RoW
- A rich set of sectoral and aggregate shocks that transmit through the global trade and production network.
- Can match observed headline inflation rates and changes in sector-level prices, wages, and exchange rates. (**nothing targeted**)
- Key Results:
  - ▶ Negative supply shocks to factors of production – labor and intermediate inputs – that can be of domestic or foreign origin, initially sparked inflation in **2020–2021**.
  - ▶ Positive aggregate demand shocks widened demand-supply imbalances and amplified inflation during **2021–2022**.
  - ▶ The reallocation of consumption between goods and service sectors transmitted the demand-supply imbalances across countries, impacting **current accounts**.
  - ▶ **Energy shocks** had differential impacts on the Euro Area relative to other countries' inflation rates, due to a higher foreign factor content of trade combined with complementarities between foreign and domestic factors of production.

# Model Sketch

# Inflation in a multicountry network-macro model

- Open economy version of Baqaee and Farhi (2022) w/simplifications:
  - ▶ Two-period multicountry model ( $n, m = 1, \dots, \mathcal{N}$ )
  - ▶ Ricardian households with perfect foresight
  - ▶ Have access to a domestic and a world bond
  - ▶ Multiple sectors ( $i, j = 1, \dots, \mathcal{J}$ ) produce using factors and intermediate inputs
  - ▶ Perfect competition in factors and good markets
  - ▶ Monetary policy: Zero-lower bound
- Frictions:
  - ▶ Downward nominal wage rigidity
  - ▶ Segmented factor markets

# Households in Country “n”: Inter-temporal Problem

$$\max_{\{C_n(0), C_n(1), B_n^W(0), B_n(0)\}} (1 - \beta)\phi_n(0) \frac{C_n(0)^{1-\sigma}}{1 - \sigma} + \beta\phi_n(1) \frac{C_n(1)^{1-\sigma}}{1 - \sigma}$$

s.t.

$$P_n(0)C_n(0) + B_n(0) + \mathcal{E}_n(0)B_n^W(0) \leq \mathcal{E}_n(0) \sum_i (W_{ni}(0)L_{ni}(0) + R_{ni}(0)\bar{K}_{ni}),$$

$$P_n(1)C_n(1) \leq \mathcal{E}_n(1) \sum_i (W_{ni}(1)L_{ni}(1) + R_{ni}(1)\bar{K}_{ni}) + (1 + i_n(0))B_n(0) + \mathcal{E}_n(1)(1 + i^W(0))B_n^W(0),$$

- $B_n$ : domestic bond denominated in local currency units (lcu). Traded domestically.
- $B_n^W$ : world bond denominated in units of fictitious world currency. Internationally traded.
- $\mathcal{E}_n$ : exchange rate between local currency and world currency (lcu per unit of world currency)
- $i_n$ : domestic interest rate
- $i^W$ : world interest rate
- $\phi_n$ : intertemporal shifter.

# Households in Country “n”: Intertemporal Optimality

- Optimality conditions

$$\frac{(1 - \beta)\phi_n(0)C_n(0)^{-\sigma}}{P_n(0)} = \frac{\beta\phi_n(1)C_n(1)^{-\sigma}(1 + i_n(0))}{P_n(1)} \quad (\text{Euler Equation})$$

$$(1 + i_n(0)) = (1 + i^W(0))\frac{\mathcal{E}_n(1)}{\mathcal{E}_n(0)} \quad (\text{Interest Parity Condition})$$

- $\bar{X}$ : steady-state value. 0 present where shocks happen, 1 future.
- From now on, assume future variables are at steady state and  $\sigma = 1$ .

# Monetary policy and exchange rates

- World interest rate is *endogenous* and determined by intertemporal shifters ( $\phi_n(0)$ )

$$(1 + i^W(0)) = \frac{(1 - \beta)}{\beta} \sum_n \bar{\alpha}_n \phi_n(0); \quad \bar{\alpha}_n = (\bar{P}_n \bar{C}_n / \bar{\mathcal{E}}_n) / \sum_m \bar{P}_m \bar{C}_m / \bar{\mathcal{E}}_m$$

- Bilateral exchange rates depend only on stance of domestic monetary policies

$$\frac{\mathcal{E}_{nm}(0)}{\bar{\mathcal{E}}_{nm}} = \frac{\mathcal{E}_n(0)}{\bar{\mathcal{E}}_n} \frac{\bar{\mathcal{E}}_m}{\mathcal{E}_m(0)} = \frac{(1 + i_m(0))}{(1 + i_n(0))}$$

- Today: set  $1 + i_n = 1$  for all countries

- ▶ No change in domestic interest rates  $\rightarrow$  Bilateral exchange rates do not change
- ▶  $\uparrow \phi_n(0) \rightarrow \uparrow (1 + i^W(0)) \rightarrow \uparrow \mathcal{E}_n(0)$ : countries depreciate *relative to the world currency*, given the parity condition

$$(1 + i_n(0)) = (1 + i^W(0)) \frac{\bar{\mathcal{E}}_n}{\mathcal{E}_n(0)}$$

# Disaggregated Consumption

- Consumption Bundle consists of Country-specific Sectoral Consumption Bundles:

$$C_n = \prod_{j=1}^{\mathcal{J}} C_{n,j}^{\Omega_{n,j}^C}, \quad \sum_{j=1}^{\mathcal{J}} \Omega_{n,j}^C = 1$$

- Country-specific Sectoral Consumption Bundles are formed by varieties (Armington aggregator)

$$C_{n,j} = \left[ \sum_{m=1}^{\mathcal{C}} (\Omega_{n,mj}^{CB})^{\frac{1}{\xi}} C_{n,mj}^{\frac{\xi-1}{\xi}} \right]^{\frac{\xi}{\xi-1}}, \quad \sum_{m=1}^{\mathcal{N}} \Omega_{n,mj}^{CB} = 1$$

# Disaggregated Production

- Sectors produce by combining the factors (value-added) and intermediate bundle.

$$\min_{\{VA_{ni}, M_{ni}\}} P_{ni}^{VA} VA_{ni} + P_{ni}^M Z_{ni}$$

s.t.

$$Y_{ni} = A_{ni} \left[ (\Omega_{ni,VA}^Y)^{\frac{1}{\theta}} VA_{ni}^{\frac{\theta-1}{\theta}} + (\Omega_{ni,Z}^Y)^{\frac{1}{\theta}} Z_{ni}^{\frac{\theta-1}{\theta}} \right]^{\frac{\theta}{\theta-1}} \quad \text{with} \quad \Omega_{ni,VA}^Y + \Omega_{ni,Z}^Y = 1$$

- Value-added bundle is composed of Labor and Capital:

$$VA_{ni} = \left[ (\Omega_{ni,L}^{VA})^{\frac{1}{\gamma}} (L_{ni})^{\frac{\gamma-1}{\gamma}} + (\Omega_{ni,K}^{VA})^{\frac{1}{\gamma}} (\bar{K}_{ni})^{\frac{\gamma-1}{\gamma}} \right]^{\frac{\gamma}{\gamma-1}} \quad \text{with} \quad \Omega_{ni,L}^{VA} + \Omega_{ni,K}^{VA} = 1$$

# Intermediate goods' aggregation

- Intermediate bundle consists of country specific sectoral bundles:

$$Z_{ni} = \left[ \sum_{j=1}^{\mathcal{J}} (\Omega_{ni,j}^Z)^{\frac{1}{\varepsilon}} X_{ni,j}^{\frac{\varepsilon-1}{\varepsilon}} \right]^{\frac{\varepsilon}{\varepsilon-1}} \quad \text{with} \quad \sum_{j=1}^{\mathcal{J}} \Omega_{ni,j}^Z = 1$$

- Country-specific Sectoral Bundles are formed by varieties (Armington aggregator):

$$X_{n,j} = \left[ \sum_{m=1}^{\mathcal{N}} (\Omega_{n,mj}^X)^{\frac{1}{\xi}} X_{n,mj}^{\frac{\xi-1}{\xi}} \right]^{\frac{\xi}{\xi-1}} \quad \text{with} \quad \sum_{m=1}^{\mathcal{N}} \Omega_{n,mj}^X = 1$$

Steel ( $j$ ) comes from country  $m = 1 \dots \mathcal{N}$  into the U.S. =  $X_{n,mj}$  as an intermediate input  
U.S. ( $n$ ) creates a steel bundle =  $X_{n,j}$  to use in different industries such as U.S. car industry =  $Z_{ni}$

# Market clearing

- Goods market clearing (as consumption or intermediate goods): for each country  $n$  sector  $i$ :

$$Y_{ni} = \sum_{m=1}^{\mathcal{N}} (X_{m,ni} + C_{m,ni})$$

# Market clearing

- Goods market clearing (as consumption or intermediate goods): for each country  $n$  sector  $i$ :

$$Y_{ni} = \sum_{m=1}^{\mathcal{N}} (X_{m,ni} + C_{m,ni})$$

- Segmented labor markets: the labor market in country  $n$ , sector  $i$

$$W_{ni} \geq \frac{\bar{W}_{ni}}{\mathcal{E}_n}, \quad \bar{L}_{ni} \geq L_{ni}, \quad (\bar{L}_{ni} - L_{ni}) \left( W_{ni} - \frac{\bar{W}_{ni}}{\mathcal{E}_n} \right) = 0$$

- ▶ Downward wage limit is given in the **local** currency but the model solves in **common** currency (e.g. Schmitt-Grohe-Uribe)
- ▶ Labor cannot go beyond the available labor and one of the constraints should be binding

# Market clearing

- Goods market clearing (as consumption or intermediate goods): for each country  $n$  sector  $i$ :

$$Y_{ni} = \sum_{m=1}^{\mathcal{N}} (X_{m,ni} + C_{m,ni})$$

- Segmented labor markets: the labor market in country  $n$ , sector  $i$

$$W_{ni} \geq \frac{\bar{W}_{ni}}{\mathcal{E}_n}, \quad \bar{L}_{ni} \geq L_{ni}, \quad (\bar{L}_{ni} - L_{ni}) \left( W_{ni} - \frac{\bar{W}_{ni}}{\mathcal{E}_n} \right) = 0$$

- ▶ Downward wage limit is given in the **local** currency but the model solves in **common** currency (e.g. Schmitt-Grohe-Urbe)
  - ▶ Labor cannot go beyond the available labor and one of the constraints should be binding
- Segmented capital markets with *no* price rigidities (always at the steady-state level):

$$K_{ni} = \bar{K}_{ni}$$

# Market clearing

- Goods market clearing (as consumption or intermediate goods): for each country  $n$  sector  $i$ :

$$Y_{ni} = \sum_{m=1}^{\mathcal{N}} (X_{m,ni} + C_{m,ni})$$

- Segmented labor markets: the labor market in country  $n$ , sector  $i$

$$W_{ni} \geq \frac{\bar{W}_{ni}}{\mathcal{E}_n}, \quad \bar{L}_{ni} \geq L_{ni}, \quad (\bar{L}_{ni} - L_{ni}) \left( W_{ni} - \frac{\bar{W}_{ni}}{\mathcal{E}_n} \right) = 0$$

- ▶ Downward wage limit is given in the **local** currency but the model solves in **common** currency (e.g. Schmitt-Grohe-Urbe)
- ▶ Labor cannot go beyond the available labor and one of the constraints should be binding
- Segmented capital markets with *no* price rigidities (always at the steady-state level):

$$K_{ni} = \bar{K}_{ni}$$

- Asset Markets clear:  $\sum_n B_n^W = 0$ 
  - ▶  $B_n^W$ , allows for endogenous current account/trade balance movements

# Segmented factor markets during collapse and recovery

- $\bar{L}_f$ : Potential level for factor  $f$ . Decrease due to sick workers, shutdowns, etc.

# Segmented factor markets during collapse and recovery

- $\bar{L}_f$ : Potential level for factor  $f$ . Decrease due to sick workers, shutdowns, etc.

# Segmented factor markets during collapse and recovery

- $\bar{L}_f$ : Potential level for factor  $f$ . Decrease due to sick workers, shutdowns, etc.
- $L_f$ : Equilibrium employment level for factor  $f$ 
  - ▶ Demand effects+downward wage rigidity  $\Rightarrow$  workers employed might be lower than *potential*
- Difference between  $\bar{L}_f$  and  $L_f$ : Keynesian unemployment

# Segmented factor markets during collapse and recovery

- $\bar{L}_f$ : Potential level for factor  $f$ . Decrease due to sick workers, shutdowns, etc.
- $L_f$ : Equilibrium employment level for factor  $f$ 
  - ▶ Demand effects+downward wage rigidity  $\Rightarrow$  workers employed might be lower than *potential*
- Difference between  $\bar{L}_f$  and  $L_f$ : Keynesian unemployment
- An increase in aggregate demand can decrease Keynesian unemployment.

# Segmented factor markets during collapse and recovery

- $\bar{L}_f$ : Potential level for factor  $f$ . Decrease due to sick workers, shutdowns, etc.
- $L_f$ : Equilibrium employment level for factor  $f$ 
  - ▶ Demand effects+downward wage rigidity  $\Rightarrow$  workers employed might be lower than *potential*
- Difference between  $\bar{L}_f$  and  $L_f$ : Keynesian unemployment
- An increase in aggregate demand can decrease Keynesian unemployment.
- During recovery: unemployment gaps are closed (heterogeneous across sectors, may not be back to 2019 but still inflationary)

# Model solution method

- Calibrate the model with ICIO 2018 Table from OECD
  - ▶ Final use shares
  - ▶ Input shares
  - ▶ Value added shares
  - ▶ Expenditures
  - ▶ Allow for initial trade imbalances
- Normalize all prices, wages and rents to 1 at steady state
- From this stable equilibrium (2019 pre-pandemic) introduce shocks
- AMPL / Knitro optimizer
- Calculate the relative changes in **common** currency
- Convert the common currency price changes to **local** currency by multiplying with the model-consistent exchange rate

# Domestic CPI inflation in a global economy

- CPI changes (where  $(\lambda^n)^T = (\Omega_n^{CS})^T \Psi$  and  $(\Lambda^n)^T = (\lambda^n)^T \Omega^F$ )

$$d \log \text{CPI}_n = \underbrace{d \log \mathcal{E}_n}_{\text{Exchange Rate}} - \underbrace{(\lambda^n)^T d \log A}_{\text{Productivity Shocks}} - \underbrace{(\Lambda^n)^T d \log L}_{\text{Factor Changes}} + \underbrace{(\Lambda^n)^T d \log \Lambda}_{\text{Local-Global D-S Imbalance}}$$

- *Exchange Rate Term* ( $d \log \mathcal{E}_n$ ): Country  $n$ 's own interest rate and inter-temporal shifter.
- *Productivity shock* ( $(\lambda^n)^T d \log A$ ): Productivity changes weighted by the importance of sector in consumption basket of country  $n$ .
- *Factor Changes* ( $(\Lambda^n)^T d \log L$ ): Labor changes weighted by the importance of factor in providing for the consumption basket of country  $n$ .
  - ▶ An endogenous object due to downward-wage rigidity.

# Domestic CPI inflation in a global economy

$$d \log \text{CPI}_n = \underbrace{d \log \mathcal{E}_n}_{\text{Exchange Rate}} - \underbrace{(\lambda^n)^T d \log A}_{\text{Productivity Shocks}} - \underbrace{(\Lambda^n)^T d \log L}_{\text{Factor Changes}} + \underbrace{(\Lambda^n)^T d \log \Lambda}_{\text{Local-Global D-S Imbalance}}$$

- *Local-Global Demand-Supply Imbalance Term*  $((\Lambda^n)^T d \log \Lambda)$ : Changes in global factor shares and local factor shares.

- ▶ Global factor shares in terms of local factor shares:

$$\Lambda_f \equiv W_f L_f = \sum_n E_n \Lambda_f^n.$$

- ▶ If  $d \log \Lambda = d \log \Lambda^n$ :

$$(\Lambda^n)^T d \log \Lambda^n = \sum_f \Lambda_f^n d \log \Lambda_f^n = \sum_f d \Lambda_f^n = d \underbrace{\sum_f \Lambda_f^n}_{=1} = 0.$$

- ▶ Endogenous object: integrates changes in demand and supply factors.
- ▶ If world demand increases in factors that also country  $n$  demands a lot, then inflationary.

# Results

# US Real Wage Changes

# Conclusion

# Difficult to Quantify Drivers of Inflation and Disinflation: Real Shocks and Policies

- **The pandemic temporarily disrupted economies:** Lockdowns and general fear of infection kept many people from working, a shift in demand away from in-person services to goods, supply chain bottlenecks.
- **Russia's invasion of Ukraine:** drove up food and energy prices worldwide, made economies temporarily poorer.
- **Fiscal and Monetary Stimulus:** Governments intervened to help the unemployed, subsidies to firms to maintain their payrolls—The purchasing power was sustained even as economies' abilities to supply goods and services temporarily fell.
  - ⇒ Inflation was the natural consequence
  - ⇒ Price increases via global factor shortages lead to domestic wage increases.

**Need a global macro-network model to understand and quantify the 2020–2023 inflation and disinflation**
